Your task is to build the latest MileauxCorporation app called MileauxChat.

A sample page of a MileauxChat window is in an HTML file in the directory. The code is not written in template form.

Your task is to completely convert the HTML file into a version that is built from templates. All of the templates should be contained within a **main** template. The rest of the templates are named as shown in this image:

Your task is to do the following:
- copy the HTML code in sampleChat.html into a series of templates named as described in the above image.
- add a helper in the chatRoomHeader template for the room name. In **templates.js**, set the template helper for roomName to be "Kibble Canyon".
- The chatMessageEntry template should contain only the form elements from the HTML file.
- The chatMessages template must be <u>inside</u> the chatMessageList template.
- In the template for chatMessages, there should be helpers for **username, imageURL,** and **message**.
- In **templates.js**, there is an array of messages, each with property names matching username, imageURL, and message. You must create a helper for the chatMessages template that uses the {{#each}} command to iterate over all of the messages. (See the notes from the last class showing how to do this.)
- If you've done this correctly, you should see the list of messages in the image above.

Grading Rubric:

| 5 | All requirements met, plus one more message in the chat window appears in the list. |
|---|---|
| 4.5 | All requirements met from above |
| 4 | Templates correctly formatted, but data not appearing |
| 3.5 | Templates incorrectly formatted |
